Decode video streams. Open and save files in ISO/MPEG-4/MPG/AVI/DIVX/XVID/MPEG-PS/VOB/MPGP/JPG/etc. iDVD for Mac is a virtual disc emulator that allows you to create a disc image of an iTunes and iMovie compatible disc. You can then create a DVD disc for your Mac from the image on your hard drive. DAEMON Tools Lite 10.12 can be downloaded and installed to a computer running Mac OS X 10.6 or later and also to a computer running Mac OS X 10.5. The present invention relates generally to optical communications and, more particularly, to a method for providing timing and modulation control in optical links. Optical links are being considered as a solution for the performance and bandwidth requirements of data networks. However, the advantages and cost savings of using optical links can only be realized if the ability to perform the following functions is provided: 1) Timing control. With sufficient timing control, multiple bits can be sent simultaneously by a single modulator. This is the common method of operating serial links. It is required to operate at high bit rates, such as 40 Gb/s or more. A higher number of bits to be transmitted in a given interval gives higher throughput and speed. 2) Modulation control. The modulation scheme is critical to achieving high data rate. A phase-shift keying (PSK) system, a 4-ary PSK (4-APSK) system, and an 8-ary PSK (8-APSK) system are common techniques used in optical links. The modulation system used has a direct impact on the ability to operate with multiple bits in a given interval. 3) Power control. The amount of power required to generate a bit is also a critical issue. Typically, a higher modulation rate requires higher average optical power, which is problematic at long distances. 4) Error detection and correction. This is an area that is receiving a lot of attention in developing optical links. Conventional optical links are typically asynchronous. Typically, the transmitter and receiver have their own clock reference that is used to sample the incoming data. In such asynchronous optical links, the timing and modulation controls described above can be supported by processing the incoming bit stream in the digital domain. In synchronous optical links, the receiver typically uses a receiver clock to sample the incoming data stream. The synchronous clock can be generated 82157476af
